

# Evanescence Integrals from local subtractions

A. Georgoudis ,

QCD meets Gravity

University of Zurich, December 12th-16th 2022

Work in collaboration with: B. Page

**NORDITA**

The Nordic Institute for Theoretical Physics

# Motivation

- Unitarity methods, beyond one loop, are always  $d$ -dimensional and require the computation of “evanescent” ( $\mu$ ) Integrals
- 4d constructions, for example the amplituhedron in  $\mathcal{N}=4$ , miss these contributions
- $\mu$ -Integrals are still rather complicated to compute using traditional methods. All-plus amplitudes are fully characterized by these contributions.

# Plan of the talk

- What are  $\mu$ -Integrals?
- Local subtractions, why  $\mu$ -Integrals are nice.
- All-plus Amplitudes from divergences:  
Planner five-point example
- Conclusions & Outlook.

# $\mu$ -Integrals

- At the integrand level decompose the loop momenta
$$l^\mu = l_4^\mu + l_{(D-4)}^\mu$$

- Amplitude integrand can then be written as

$$A^{(e)} = A_{4D}^{(e)} + \mu[A^{(e)}] \longrightarrow \mu_{ij} = l_i^{(D-4)} \cdot l_j^{(D-4)}$$

- $\mu[A^{(e)}]$  naively should be  $O(\epsilon)$  but actually worse due to divergences in integration region!
- At 1-loop they can be understood as dim-shifts.

$$\int^d (f(\epsilon) \mu_{ii}^2) = \frac{(d-4)(d-2)}{4} \int^{d+4} [f(\epsilon)]$$

# Plan of the talk

- What are  $\mu$ -Integrals?
- Local subtractions, why  $\mu$ -Integrals are nice.
- All-plus amplitudes from divergences:  
Planar 5-point example.
- Conclusions and outlook

# Type of Divergences

- Singular integration regions usually associated to
  - large  $l \rightarrow UV$
  - small  $l \rightarrow IR$  (soft)
  - $l$  collinear to ext momenta  $\rightarrow IR$  (collinear)
- Our statement is that these regions fully determine  $\mu$ -Integrals up to  $O(\epsilon)$  terms!

# IR soft

- Can be extracted by expanding around vanishing propagators.

- Starting integral is **IR convergent** if  $N(0, \mu_{11}) \neq N(0, 0)$ , otherwise we obtain:

$$\frac{N(0, 0)}{(p_1 + p_2)^2} \approx \frac{1}{st\epsilon^2} + \frac{1}{st\epsilon} \log(t) + \dots$$

soft pole                      ?

# IR collinear

- Region associated with  $\ell_i = x p_i$ , local subtraction found by [Anastasiou, Sterman 18], requires an integration (transverse loop momenta).

collinear Region exists only for  $N(\ell, 0)$

$$\frac{1}{\epsilon} \int_0^1 dx \frac{N(x p_i)}{s x t (1-x)}$$

- Integral is divergent, when extracting collinear region need to act on soft subtracted Integral:

$$C_1 (1 - S_{12} - S_{14}) \text{II} \Rightarrow C_1 \left( \text{II}_1^3 - \text{II}_1^2 - \text{II}_1^3 - \text{II}_1^2 \right) \approx \frac{1}{\epsilon} \int_0^1 dx \left[ \frac{1}{s x t (1-x)} - \frac{1}{s t (1-x)} - \frac{1}{s x t} \right] + \text{prescription}$$

UV

We have seen how IR divergences get suppressed when we have  $\mu_{II}$  in the numerator.

Expand for large  $\ell$

$$\int d^d \ell \frac{N(\mu_{II})}{(\ell^2 - m^2)^4} = \mathcal{O}(N(\mu_{II}))$$

Power counting to see what happens:  $4 - \# \text{exponent of } \mu_{II} - \frac{d}{2}$

$\mu_{II}^2$  first UV divergence!

# Why Nice!

- Regions with  $\mu$ -terms, if they contribute, can only be **UV**!
- At two-loops, many more combinations but divergences only 1-loop like.

$$I^{2\text{-loop}}[\mu_{ij}] = \tilde{T}_{IR} I^{2\text{-loop}}[\mu_{ij}] + (1 - \tilde{T}_{IR}) \tilde{T}_{UV} I^{2\text{-loop}}[\mu_{ij}] + O(\epsilon)$$

$$\tilde{T}_{IR} : S_{\text{soft}} + \text{collinear} \\ \sum_{ij} S_{ij} + \frac{\sum_k C_k (1 - S_{ij})}{\sum_k \bar{C}_k}$$

$$\tilde{T}_{UV} : \text{UV region, large loop} \\ \text{momenta expansion.}$$

# Examples

- Let us apply our procedure to some 4-point examples

$$\begin{array}{c}
 \begin{array}{c} 2 \\ \hline \mu_{11}^2 \\ \hline 1 \end{array} \begin{array}{c} 3 \\ \hline \\ \hline 4 \end{array} = \underbrace{\begin{array}{c} 2 \\ \hline \mu_{11}^2 \\ \hline 1 \end{array} \begin{array}{c} 3 \\ \hline \\ \hline 4 \end{array}}_{\text{Soft}} \frac{1}{s} + \underbrace{\frac{1}{s\epsilon} \int_0^1 \left[ \frac{dx}{1-x} \right]_+ \begin{array}{c} 2 \\ \hline \mu_{11}^2 \\ \hline 1 \end{array} \begin{array}{c} 3 \\ \hline (1-x)4 \\ \hline x4 \end{array} + \frac{1}{s\epsilon} \int_0^1 \left[ \frac{dx}{x} \right]_+ \begin{array}{c} 2 \\ \hline \mu_{11}^2 \\ \hline 1 \end{array} \begin{array}{c} 3 \\ \hline (1-x)3 \\ \hline x4 \end{array}}_{\text{Collinear}}
 \end{array}$$

$$\begin{array}{c} 2 \\ \hline \mu_{11}^2 \\ \hline 1 \end{array} \begin{array}{c} 3 \\ \hline \\ \hline 4 \end{array} = \frac{1}{\epsilon} \int_0^1 dx \begin{array}{c} 2 \\ \hline \mu_{11} \\ \hline 1 \end{array} \begin{array}{c} 3 \\ \hline \\ \hline (1-x)3 \end{array} + 4 \leftrightarrow 3$$

- In the second case the  $\mu$ -Integral localizes onto a 1-loop integration

# Plan of the talk

- Local subtractions, why  $\mu$ -Integrals are nice.
- All-plus amplitudes from divergences:  
Planar 5-point example.
- Conclusions and outlook

# All plus Amplitudes: 5-point Example

- Amplitude is known, we will focus on planar contributions.
- Weight drop in the amplitude manifest only after combining all pieces together.  **$\mathcal{M}$ -Integrals can still be weight 4**

$$\mathcal{A}^{(2)}(1^+, 2^+, 3^+, 4^+, 5^+) = ig^7 \sum_{\sigma \in S_5} \sigma \circ I \left[ C \left( \begin{array}{c} 5 \\ 4 \end{array} \begin{array}{c} 1 \\ 2 \\ 3 \end{array} \right) \left( \underbrace{\left( \frac{1}{2} \Delta \left( \begin{array}{c} 5 \\ 4 \end{array} \begin{array}{c} 1 \\ 2 \\ 3 \end{array} \right) + \Delta \left( \begin{array}{c} 5 \\ 4 \end{array} \begin{array}{c} 1 \\ 2 \\ 3 \end{array} \right) + \frac{1}{2} \Delta \left( \begin{array}{c} 5 \\ 4 \end{array} \begin{array}{c} 1 \\ 2 \\ 3 \end{array} \right)}_{\text{Non-factorizable}} \right. \right. \\
 \left. \left. + \frac{1}{2} \Delta \left( \begin{array}{c} 5 \\ 4 \end{array} \begin{array}{c} 1 \\ 2 \\ 3 \end{array} \right) + \Delta \left( \begin{array}{c} 5 \\ 4 \end{array} \begin{array}{c} 1 \\ 2 \\ 3 \end{array} \right) + \frac{1}{2} \Delta \left( \begin{array}{c} 5 \\ 4 \end{array} \begin{array}{c} 1 \\ 2 \\ 3 \end{array} \right) \right) \right]$$

[Badger, Mogull, Ochirov, O'Connell 15]

factorizable

- Form of the Amplitude Known [Gehrmann, Hepp, Lopresti 15]

$$A_4^{(2)} = I^{(1)} A^{(1)} + F_{\text{polylog}}^{(2)} + F_{\text{rational}}^{(2)}$$

- Integrands depend on  $\mu_{12}$  in a particular combination

$$F_1 = (D_s - 2)(\mu_{11}\mu_{22} + (\mu_{11} + \mu_{22})^2 + 2(\mu_{11} + \mu_{22})\mu_{12}) + 16(\mu_{12}^2 - \mu_{11}\mu_{22}),$$

$$F_2 = 4(D_s - 2)(\mu_{11} + \mu_{22})\mu_{12},$$

$$F_3 = (D_s - 2)^2 \mu_{11}\mu_{22}.$$

← Non factorizable

} factorizable

- $F_2$  only  $\mu_{11}^2, \mu_{22}^2$  will contribute, both IR and UV
- $F_2, F_3$  only contribute to UV!

- We can uplift our approach for  $\mu$ -Integrals to the full amplitude

$$A_+^{(2)} = \gamma_{IR} A_+^{(2)} + (1 - \gamma_{IR}) T_{uv} \left[ A_{\text{non fact}}^{(2)} + A_{\text{fact}}^{(2)} \right]$$

$$\gamma_{IR} = \sum_{I_3} S_{I_3} + \sum_K \bar{C}_K$$

- Relating them to the known results:

$$-\sum_{I_3} S_{I_3} A_+^{(2)} = I^{(1)} A^{(2)}$$

$$-\bar{C}_K A_+^{(2)} = 0$$

$$-(1 - \gamma_{IR}) T_{uv} A_{\text{non fact}}^{(2)} = F_{\text{poly log}}^{(2)}$$

$$-(1 - \gamma_{IR}) T_{uv} A_{\text{fact}}^{(2)} = F_{\text{rational}}^{(2)}$$

- We can uplift our approach for  $\mu$ -Integrals to the full amplitude

$$A_+^{(2)} = \gamma_{IR} A_+^{(2)} + (1 - \gamma_{IR}) T_{UV} \left[ A_{\text{non fact}}^{(2)} + A_{\text{fact}}^{(2)} \right] \quad \gamma_{IR} = \sum_{I_3} S_{I_3} + \sum_K \bar{C}_K$$

- Relating them to the known results:

$$-\sum_{I_3} S_{I_3} A_+^{(2)} = I^{(1)} A^{(2)}$$

$$-\bar{C}_K A_+^{(2)} = 0$$

$$-(1 - \gamma_{IR}) T_{UV} A_{\text{non fact}}^{(2)} = F_{\text{poly log}}^{(2)}$$

$$-(1 - \gamma_{IR}) T_{UV} A_{\text{fact}}^{(2)} = F_{\text{rational}}^{(2)}$$

- We can uplift our approach for  $\mu$ -Integrals to the full amplitude

$$A_+^{(2)} = \gamma_{IR} A_+^{(2)} + (1 - \gamma_{IR}) T_{uv} \left[ A_{\text{non fact}}^{(2)} + A_{\text{fact}}^{(2)} \right] \quad \gamma_{IR} = \sum_{I_3} S_{I_3} + \sum_K \bar{c}_K$$

- Relating them to the known results:

$$-\sum_{I_3} S_{I_3} A_+^{(2)} = I^{(1)} A^{(2)}$$

$$-\bar{c}_K A_+^{(2)} = 0$$

$$-(1 - \gamma_{IR}) T_{uv} A_{\text{non fact}}^{(2)} = F_{\text{poly log}}^{(2)}$$

$$-(1 - \gamma_{IR}) T_{uv} A_{\text{fact}}^{(2)} = F_{\text{rational}}^{(2)}$$

Once IR subtracted  
finite 1-man box!

# Plan of the talk

- What are  $\mu$ -Integrals?
- Local subtractions, why  $\mu$ -Integrals are nice.
- All-plus amplitudes from divergences:  
Planar 5-point example.
- Conclusions and outlook

# Conclusions & Outlook

- Implemented [Anastasiou, Sterman 18] for  $\mu$ -Integrals.
  - Explicitly shown cancellation of collinear contributions and understood structure of finite remainder.
- 
- Apply this method to higher point Amplitudes and beyond All-plus.
  - Can we construct  $\mu$ -parts of the amplitude with the same nice factorization property?

Thank you!
